

Can you verify a bank balance — without seeing it?

Welcome to the **TLSNotary Demo**
Live at **Devconnect**

The Problem

We trust web data every day —
but we can't *prove* it.

When a website shows balances or records,
there's no cryptographic way to verify it's genuine.

The Idea

TLSNotary makes HTTPS *provable*.

Using **MPC-TLS**, we can produce a cryptographic proof
of what a website actually said —
without revealing secrets.

The Demo

Help us verify the Ethereum Foundation's Swiss Bank balance

- 1** Join the Wi-Fi: **TLSNotary / tlsnotary**
- 2** Open **devconnect.tlsnotary.org**
- 3** Click **Verify**

(QR codes appear on booth sign)

What Happens Under the Hood

A cryptographic handshake — without trust.

The booth connects to a real TLS server,
splits the handshake between two parties
(Prover & Verifier),

and generates a verifiable proof of the server's response.

Why It Matters

Web proofs for the next generation of apps:

- Privacy-preserving verification of off-chain data
- Auditable financial statements
- On-chain verifiable facts from any website

Bridging **the Web and Ethereum** — privately.
